

The multifactor model

Pre-registered selection and weighting, out of sample 2016–2026

Beats owning everything by +1.3% a year (t 1.0): not enough to pass its own bar.

I wrote the rules down before I ran the model. Here is what happened.

FS14 is the last step of the factsheet series: take 25 market-neutral factor books (19 price signals in six markets, plus six US fundamental themes), and every month, using only the past:

- keep the books with a credible 3-year record (probabilistic Sharpe ≥ 0.8 , costs under half the gross spread),
- drop near-duplicates (correlation above 0.7),
- weight what is left (11 pre-registered rules, from equal weights to 60-month exponential mean/variance).

The bar, set in advance: beat owning all 25 books equally with $t > 2$, and in both 2016–19 and 2020–26.

Result: +1.3% a year better (t 1.0), positive in both periods, in 4 of 5 markets. Not enough. The claim fails its own test.

Two more honest findings:

- A fixed shortlist of low beta and momentum (plus profit growth and debt issuance in the US) did better, but I picked it after seeing the data.
- None of these market-neutral books came close to simply owning the market over the same years.

After 682 tests across 14 factsheets, that is the lesson: discipline protects you from fooling yourself more than it finds alpha.
